the game itself is a standard shooter, but the replayability is what makes this game special. there are unlockable character classes, character progression systems, and a leveling system that allows you to increase your character's health, resistances, and damage output. the level cap is 100, and players can unlock up to 30 different characters. each character is given a number to identify them. each of these numbers can be upgraded three times; the upgrade costs nothing, but you can only upgrade a character once every three hours. once again, it is extremely easy to create, and the tool is fully responsive. a side-by-side comparison with other drafting apps shows that this one is a real winner. other features include support for editable schematics, a nice variety of text styles, and the ability to convert the schematic into a circuit board layout. the software also allows you to import circuit board files and provides easy access to other engineering documents, including boms, line lists, and bill of materials. the software is a bit of a mixed bag. there are some issues with the interface, but most of those issues are due to some odd choices the developers have made. we'd like to have seen some sort of an update to the user interface. despite some usability issues, the new tcl script integration in the newest version of arcpad pro is fantastic. it's very easy to create custom scripts that allow you to perform many types of measurements and calculations, and to automate repetitive tasks. you're allowed to freely control the footprint of the components of the board, and then the software takes care of the rest. it's a great feature for a professional pcb designer. we tested the board design functionality, and all the boards designed with the program performed well. arcpad pro also provides a tcl script functionality, which is very easy to set up. we used the script to generate a footprint for a couple of components, and the results were excellent. the fact that we were using a tcl script does mean that we have to use the command line to generate the footprint, and we found it to be a little annoying. the easiest way to generate a footprint is to type the command directly into the command line, but in order to do that, we have to know the exact physical dimensions of the board. we did not find a way to take a physical measurement of the board and then use that value in the script. the software does have a tcl script functionality, but the process is a little confusing. the way we found to generate a footprint is to first choose which component you want to use, then choose what surface the footprint should be generated on. we are assuming that the footprint should be generated on a single layer. next, we choose the size of the footprint, and the software gives us a list of sizes available. we choose a footprint size, and then we choose what material to use for the footprint. the software then generates the footprint. it is very easy to generate a footprint, and it is the easiest tool we have tested so far. the tool is available as a paid app, and the price is very reasonable.
